The Impact of Maltreatment on the Developing Child

Dana M. Hagele, MD, MPH

Overview

Childhood, from infancy to adolescence, is a time of enormous neurological growth and development. Child maltreatment—including physical, sexual, and emotional abuse; neglect; and exposure to domestic violence—represents an extreme traumatic insult to the developing child. Specifically, maltreatment results in disruption of the bond between child and caregiver, and it causes up-regulation of the biological stress response system. Chronic traumatic exposure may then lead to persistent changes in brain structure and chemistry. Current research suggests that these biological alterations contribute to long-term physical, emotional, behavioral, developmental, social, and cognitive dysfunction seen in adults who have experienced childhood maltreatment. As described by DeBellis, the “psychobiological sequelae of child maltreatment may be regarded as an environmentally induced, complex developmental disorder.”

Child Maltreatment: Biological Pathways to Adverse Outcomes

Immediate Alterations in Brain Chemistry

The psychological trauma of maltreatment triggers the complex neurochemical and hormonal systems involved in the stress response and in emotional regulation. When a child experiences an abusive insult, in their glucocorticoid, noradrenergic, and vasopressin-oxytocin systems are activated; this highly adaptive response allows for survival in a dangerous environment. Chronic activation, however, may result in permanent changes in brain chemistry, structure, and function. Over time, maltreated children are at risk for the development of an exaggerated response to relatively minor stress. Compounding this insult, maltreated children are forced to respond to environmental threats (family violence), rather than engaging in activities necessary for the development of complex emotional, behavioral, and cognitive functioning.

Recent neuroimaging studies demonstrate that neuroanatomy is significantly altered among individuals who have experienced childhood maltreatment and abuse-related Posttraumatic Stress Disorder.

Persistent Alterations in Brain Structure and Function

Recent neuroimaging studies demonstrate that neuroanatomy is significantly altered among individuals who have experienced childhood maltreatment and abuse-related Posttraumatic Stress Disorder.

For example, children diagnosed with maltreatment-related PTSD have reduced cerebral volume (prefrontal white matter, right temporal lobe, and mid-section of the corpus callosum), and associated enlargement of the ventricular system. This finding indicates significant neuronal loss, and therefore, lost potential for child growth, development, and functioning. Studies have shown alterations in the pituitary and hippocampus of children with PTSD; this demonstrates a possible link between the trauma of child abuse, resultant changes in brain anatomy, and adverse effects on learning and memory.

Chronic or extreme maltreatment may result in altered neurophysiology and neuroanatomy through persistent activation of the hypothalamic-pituitary-adrenal axis (HPA) and the catecholamine stress system. For example, women with a history of childhood sexual abuse exhibit HPA-axis abnormalities (cortisol suppression following dexamethasone challenge) comparable to that of adults with combat-related PTSD. Similarly,
children with a history of sexual abuse show evidence of higher catecholamine functional activity, which manifests as physiological agitation.\textsuperscript{9} Finally, children with a history of maltreatment-associated PTSD demonstrate characteristic changes in cerebral blood flow patterns,\textsuperscript{10} as well as characteristic alterations in regional activation of the brain.\textsuperscript{11} These findings offer a neurophysiological explanation for the behavioral and emotional changes seen in children with histories of abuse.\textsuperscript{12}

**Child Maltreatment: Intermediate and Long-Term Outcomes**

**Impact on Child, Family, Community, and Society**

Child maltreatment, and the associated disruption of secure parent-child attachment, represents a severe traumatic exposure comparable to that of military combat. The initial physiological and behavioral response to abuse may be appropriate and adaptive. However, if the trauma is severe or chronic, persistent changes in neuroanatomy and neurophysiology may occur, often leading to the development of psychiatric disturbance, particularly depression and PTSD. Ultimately, maltreatment and its associated morbidities predict adverse short- and long-term outcomes across physical, developmental, cognitive, emotional, behavioral, and social functional domains.

**General Medical Problems and High-Risk Health Behaviors**

Adults and adolescents with a history of childhood abuse, neglect, or domestic violence exposure, demonstrate nearly twice the number of serious health problems as children without these experiences.\textsuperscript{13} Documented medical problems associated with childhood maltreatment include: chronic fatigue;\textsuperscript{14} altered thyroid function;\textsuperscript{15} altered immune function;\textsuperscript{16} eating disorders and obesity;\textsuperscript{17} asthma;\textsuperscript{18} hypertension,\textsuperscript{19} and peptic ulcer disease.\textsuperscript{20} Similarly, these exposures increase the likelihood of high-risk health behaviors among men and women, including: a higher number of lifetime sexual partners;\textsuperscript{19} increased male involvement in teen pregnancies;\textsuperscript{20} higher incidence of unprotected sex with partners of unknown HIV status;\textsuperscript{21} younger age at first voluntary intercourse;\textsuperscript{22} diminished birth control efficacy;\textsuperscript{23} younger age at the birth of the first child;\textsuperscript{24} and greater likelihood of becoming a teen mother.\textsuperscript{22} Similarly, childhood maltreatment is predictive of significantly higher levels of alcohol and substance abuse disorders.\textsuperscript{25,27}

**Developmental Dysfunction and Mental Health Disorders**

Children with a history of maltreatment frequently demonstrate significant deficits across developmental and cognitive domains, ultimately affecting educational performance. Specifically, maltreated children demonstrate deficits in attention, abstract reasoning, impulse control, and long-term memory for verbal information.\textsuperscript{12} Similarly, traumatic exposure is associated with significant decrease in IQ.\textsuperscript{28} Due to overlapping cognitive, behavioral, and emotional symptomatology, childhood PTSD may resemble Attention-Deficit Hyperactivity Disorder (ADHD) or other learning disabilities in the classroom.

Child abuse and neglect are independently associated with the development of adolescent and adult mental health disorders. This effect is mediated, in part, through persistent stimulation of biological stress systems, as well as through the development of PTSD. Mood and anxiety disorders are most prevalent among this population;\textsuperscript{29,30} between one-third and one-half of all abused children meet the Diagnostic and Statistical Manual of Mental Disorders criteria for PTSD.\textsuperscript{31,32} In addition to the development of mental health disorders, maltreatment is associated with the development of co-morbid personality disorders.\textsuperscript{33} Overall, child maltreatment and associated co-morbidities are independent risk factors for suicidal thoughts and behavior.\textsuperscript{33,36} By eight years of age, approximately 10% of maltreated children experience suicidal ideation.\textsuperscript{37}

**Re-victimization and Dysfunctional Parenting**

A childhood history of maltreatment is associated with dysfunctional interpersonal relations in adulthood. Compared to individuals who have not been abused, adults with a childhood history of abuse and neglect report twice as many subsequent sexual assaults, higher rates of domestic violence, and four times the incidence of self-harm.\textsuperscript{38,39} Chronic, severe maltreatment is independently associated with re-victimization, including later involvement in intimate partner violence.\textsuperscript{39} This outcome may be mediated through the development of cognitive distortions, learned in the context of child maltreatment.\textsuperscript{40} Similarly, child maltreatment independently predicts later dysfunction in parenting, including the perpetration of severe physical maltreatment\textsuperscript{41} and inappropriate maternal dependence on children for emotional fulfillment.\textsuperscript{42} These findings may contribute to the intergenerational transmission of maltreatment.

**Adverse Societal Effects**

Child maltreatment and associated morbidities independently predict child and familial dysfunction across physical, developmental, emotional, behavioral, cognitive, and social domains. Thus, maltreatment—both directly and indirectly—has a profound, adverse effect on societal health and functioning. Specifically, child abuse and neglect are correlated with increased prevalence of public health problems, including community and domestic violence, delinquency, mental health disorders, alcohol and illicit substance use, obesity, suicide, and teen pregnancy. These outcomes, in turn, correlate with increased utilization of public and private resources. For example, individuals with childhood histories of maltreatment participate in more emergency room and general medical evaluations.\textsuperscript{43} They also demonstrate higher utilization rates with regard to

a “The Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition” (DSM IV) is the manual physicians, psychiatrists, psychologists, therapists, and social workers use to diagnose mental illness.
inpatient and outpatient psychiatric services, as well as surgical hospitalizations. 44-46 In addition to direct healthcare costs, maltreatment and its sequelae result in incalculable expenditures across the child welfare, public and private mental health, early intervention and education, juvenile delinquency and criminal justice, public welfare, and public health systems.

**Adverse Affect of Maltreatment on the Developing Child: Public Health Implications**

Physiological and psychological response to stress, including maltreatment, is often adaptive, allowing for the preservation of individual safety and integrity. With chronic or extreme traumatic exposure, this response may become highly maladaptive, resulting in further child and family dysfunction. Ultimately, child and family dysfunction impacts community and societal well-being. Thus, the optimal public health response to child maltreatment necessitates policies and practices supportive of evidence-based primary prevention efforts, early detection through screening and evaluation, prompt stabilization of child and family safety and well-being, and initiation of appropriate intervention and therapy.
